PHOTON CORRELATIONS*

Roy J. Glauber

Lyman Laboratory, Harvard University, Cambridge, Massachusetts

(Received 27 December 1962)

In 1956 Hanbury Brown and Twiss¹ reported that the photons of a light beam of narrow spectral width have a tendency to arrive in correlated pairs. We have developed general quantum mechanical methods for the investigation of such correlation effects and shall present here results for the distribution of the number of photons counted in an incoherent beam. The fact that photon correlations are enhanced by narrowing the spectral bandwidth has led to a prediction² of large-scale correlations to be observed in the beam of an optical maser. We shall indicate that this prediction is misleading and follows from an inappropriate model of the maser beam. In considering these problems we shall outline

a method of describing the photon field which appears particularly well suited to the discussion of experiments performed with light beams, whether coherent or incoherent.

The correlations observed in the photoionization processes induced by a light beam were given a simple semiclassical explanation by Purcell,³ who made use of the methods of microwave noise theory. More recently, a number of papers have been written examining the correlations in considerably greater detail. These papers^{2,4-6} retain the assumption that the electric field in a light beam can be described as a classical Gaussian stochastic process. In actuality, the behavior of the photon field is considerably more

PARTICLE PHYSICS

PHYSICAL REVIEW

VOLUME 120, NUMBER 1

OCTOBER 1, 1960

Influence of Bose-Einstein Statistics on the Antiproton-Proton Annihilation Process*

GERSON GOLDBABER, SULAMITH GOLDBABER, WONYONG LEE, AND ABRAHAM PAIS†

Lawrence Radiation Laboratory and Department of Physics, University of California, Berkeley, California

(Received May 16, 1960)

Recent observations of angular distributions of π mesons in $\bar{p}$ - p annihilation indicate a deviation from the predictions of the usual Fermi statistical model. In order to shed light on these phenomena, a modification of the statistical model is studied. We retain the assumption that the transition rate into a given final state is proportional to the probability of finding N free π mesons in the reaction volume, but express this probability in terms of wave functions symmetrized with respect to particles of like charge. The justification of this assumption is discussed. The model reproduces the experimental results qualitatively, provided the radius of the interaction volume is between one-half and three-fourths of the pion Compton wavelength; the depend-

ence of angular correlation effects on the value of the radius is rather sensitive. Quantitatively, there seems to remain some discrepancy, but we cannot say whether this is due to experimental uncertainties or to some other dynamic effects. In the absence of information on π - π interactions and of a fully satisfactory explanation of the mean pion multiplicity for annihilation, we wish to emphasize the preliminary nature of our results. We consider them, however, as an indication that the symmetrization effects discussed here may well play a major role in the analysis of angular distributions. It is pointed out that in this respect the energy dependence of the angular correlations may provide valuable clues for the validity of our model.

HBT Interferometry: Historical Perspective

Sandra S. Padula

Instituto de Física Teórica - UNESP, Rua Pamplona 145, 01405-900 São Paulo, Brazil

Received on 15 December, 2004

I review the history of HBT interferometry, since its discovery in the mid 1950's, up to the recent developments and results from BNL/RHIC experiments. I focus the discussion on the contributions to the subject given by members of our Brazilian group.

1.2 GGLP

In 1959, Goldhaber, Goldhaber, Lee and Pais performed an experiment at the Bevalac/LBL, in Berkeley, CA, USA, aiming at the discovery of the ρ^0 resonance[4]. In the experiment, they considered $\bar{p}p$ collisions, at 1.05 GeV/c. They were searching for the resonance by means of the decay $\rho^0 \rightarrow \pi^+\pi^-$, by measuring the unlike pair, $\pi^+\pi^-$, mass-distribution and comparing it with the ones for like pairs, $\pi^\pm\pi^\pm$. Afterwards, they concluded that there was not enough statistics for establishing the existence of ρ^0 . Nevertheless, they observed an unexpected angular correlation among identical pions! Later, in 1960, they successfully reproduced the empirical angular distribution by a detailed multi- π phase-space calculation using symmetrized wave functions for LIKE particles. Being so, they concluded the effect was a consequence of the Bose-Einstein nature of $\pi^+\pi^+$ and $\pi^-\pi^-$. They were not aware of the experiment Hanbury-Brown and Twiss had performed previously. Thus, they had discovered, by chance, the counterpart of the HBT effect in high energy collisions.

Figure 3. Simplified picture: two point sources, I and II, emit quanta considered as plane waves, which are observed in detectors A and B, respectively, with momenta k_1^μ and k_2^μ . Since the quanta are indistinguishable, there are two possible combinations for this observation, illustrated by the two continuous and the two dashed lines.

Review of HBT or Bose-Einstein correlations in high energy heavy ion collisions

T. Csörgő

MTA KFKI RMKI, H - 1525 Budapest 114, P.O.Box 49, Hungary

Abstract. A brief review is given on the discovery and the first five decades of the Hanbury Brown–Twiss effect and its generalized applications in high energy nuclear and particle physics, that includes a meta-review. Interesting and inspiring new directions are also highlighted, including for example source imaging, lepton and photon interferometry, non-Gaussian shape analysis as well as many other new directions. Existing models are compared to two-particle correlation measurements and the so-called RHIC HBT puzzle is resolved. Evidence for a (directional) Hubble flow is presented and the conclusion is confirmed by a successful description of the pseudorapidity dependence of the elliptic flow as measured in Au+Au collisions by the PHOBOS Collaboration.

THE PHYSICS OF HANBURY BROWN–TWISS INTENSITY INTERFEROMETRY: FROM STARS TO NUCLEAR COLLISIONS *

GORDON BAYM

Department of Physics, University of Illinois at Urbana-Champaign
1110 W. Green St., Urbana, IL 61801, USA

(Received April 14, 1998)

In the 1950's Hanbury Brown and Twiss showed that one could measure the angular sizes of astronomical radio sources and stars from correlations of signals. Their subsequent application to the study of photon and neutron quantum statistics has become a powerful tool in many fields. The effect is of course the basic principle of the laser and the maser, and it is of course the basis of the quantum theory of light and of the quantum theory of matter and of the quantum theory of the solid state.

Bose–Einstein effects and W mass determinations

Leif Lönnblad, Torbjörn Sjöstrand¹

Theory Division, CERN, CH-1211 Geneva 23, Switzerland

Received 30 January 1995

Editor: R. Gatto

Abstract

In $e^+e^- \rightarrow W^+W^- \rightarrow q\bar{q}_1 q\bar{q}_2$ events at LEP 2, the two W decay vertices are much closer to each other than typical hadronization distances. Therefore the Bose–Einstein effects, associated with the production of identical bosons (mainly pions), may provide a ‘cross-talk’ between the W^+ and the W^- decay products. If so, the observable W masses are likely to be affected. We develop algorithms for the inclusion of Bose–Einstein effects in multi-hadronic events. In this way we can study potential uncertainties in the W mass determination. In some scenarios the effects are significant, so that this source of uncertainty cannot be neglected.

TWO-PARTICLE CORRELATIONS IN RELATIVISTIC HEAVY-ION COLLISIONS

Key Words HBT, intensity interferometry, heavy ion collisions, femtoscopy

■ **Abstract** Analyses of two-particle correlations have provided the chief means for determining spatio-temporal characteristics of relativistic heavy ion collisions. We discuss the theoretical formalism behind these studies and the experimental methods used in carrying them out. Recent results from RHIC are put into context in a systematic review of correlation measurements performed over the past two decades. The current understanding of these results is discussed in terms of model comparisons and overall trends.

Temporal intensity correlation measured for three different stars. Gaussian fits are dashed.

Laboratory simulations

End-to-end operation of intensity interferometry in the laboratory: artificial stars; telescope array; photon-counting detectors; reconstructed images.

Artificial stars in laboratory intensity interferometer

Diffraction patterns with laser light show the [squared] Fourier transforms of some artificial 'stars'. Circular single star; elliptic small single star; binary with equal components. Image widths correspond to ~70 cm in the telescope plane and such baselines are required to retrieve these patterns.

(D.Dravins, T.Lagadec, P.Nuñez, *Astron.Astrophys.* **580**, A99, 2015)

How to make an artificial star?

S/N in intensity interferometry depends not only on instrumentation but also on the source brightness temperature

Laboratory Intensity Interferometer (Lund Observatory)

Left: Light from a 300 mW λ 532 nm laser is randomized through scattering against microscopic particles in a square-top cuvette and focused by a condenser onto artificial 'stars', being apertures in a rotatable holder. **Right:** The 'stars' are observed by an array of small telescopes, each with a photon-counting SPAD detector. 2-D coverage is achieved by rotating the asymmetric source relative to the plane of the telescopes.

(D.Dravins, T.Lagadec, P.Nuñez, *Astron.Astrophys.* **580**, A99, 2015)

Laboratory intensity interferometry with few baselines

Second-order coherence $g(2)$ measured for artificial single stars of different angular sizes. Superposed are Airy functions for circular apertures (squared moduli of the Fourier transforms).

(D.Dravins, T.Lagadec, P.Nuñez, *Astron.Astrophys.* **580**, A99, 2015)

Laboratory intensity interferometry with many baselines

Second-order coherence $g(2)$ for an artificial binary star with each component of diameter ~ 1 arcsec.

This coherence surface was produced from intensity correlations measured across 60 different non-redundant baselines, illustrating how a telescope array fills in the interferometric plane. The central maxima (left) indicate the binary separation while the symmetric rings reveal the size of individual stars.

(D.Dravins, T.Lagadec, P.Nuñez, *Astron.Astrophys.* **580**, A99, 2015)

Laboratory intensity interferometry with 100 baselines

Intensity interferometry measurements with 100 different telescopic baselines. The data largely fill the interferometric (u,v) -plane of the second-order coherence $g(2)$ for an artificial star, somewhat irregular and elliptic, with angular extent just below 1 arcsecond. At right, the projection of the 3-D mesh is oriented straight down, showing [the modulus of] the source's Fourier transform ('diffraction pattern').

(D.Dravins & T.Lagadec, Proc. SPIE **9146**, 2014)

Laboratory intensity interferometry with 180 baselines

Measured second-order spatial coherence $g^{(2)}$ from intensity interferometry over 180 telescopic baselines. The source is an artificial binary star with differently large components. The structure corresponds to the pattern that would be produced by coherent light undergoing diffraction in a corresponding aperture.

(D.Dravins, T.Lagadec, P.Nuñez, *Astron.Astrophys.* **580**, A99, 2015)

Image reconstruction

Second-order coherence $g^{(2)}$

$$g^{(2)}(\tau) = 1 + |g^{(1)}(\tau)|^2$$

Does not retain phase information,
direct image reconstruction not possible.

Imaging requires retrieval of
Fourier phases from amplitudes.

Feasible if dense coverage of (u,v)-plane

Image reconstruction from intensity interferometry

This Airy-disk diffraction pattern is immediately recognized as originating in a circular aperture, although only intensities are recorded.

Two-dimensional images can be reconstructed without phase information, provided two-dimensional coverage of the (u,v) -plane is available

Image reconstructions from intensity interferometry

Optical images reconstructed from intensity interferometry.
Measurements with 100 and 180 baselines, of an elliptical 'star', and a binary with brightness ratio 1:4.

Abstract: We have developed a technique for imaging dark, i.e. non-radiating, objects by intensity interferometry measurements using a thermal light source in the background. This technique is based on encoding the dark object's profile into the spatial coherence of such light. We demonstrate the image recovery using an adaptive error-minimizing Gerchberg-Saxton algorithm in case of a completely opaque object, and outline the steps for imaging purely refractive objects.

Results of simple image recovery algorithm

CTA Potential

Cherenkov Telescope Array as an Intensity Interferometer

Expected resolution for assumed exoplanet transit across the disk of Sirius

Stellar diameter = 1.7 solar

Distance = 2.6 pc

Angular diameter = 6 mas

Assumed Jupiter-size planet with rings;
four Earth-size moons;
equatorial diameter = 350 μ as.

CTA array spanning 2 km;

Resolution 50 μ as at λ 400 nm provides more than 100 pixels across the stellar diameter

THE FIRST THREE LARGE SATELLITES OF JUPITER IN TRANSIT

Upper—Satellite I, Antoniadi's observations, completed by details discovered by Barnard.

Middle—Satellite II, as seen by Antoniadi Sept. 28, 1927.

Lower—Satellite III, as seen by Antoniadi, with whitish southern spot seen by Barnard.
