

# QCD THERMODYNAMICS

(Approaching the continuum limit:  $N_f=4,6,8,10$  or  $a \approx 0.3, 0.2, 0.15, 0.12$  fm)

Z. Fodor

1. Introduction
2. The nature of the transition: broad cross-over
3. The transition temperature:  $T_c$
4. Static potential as a function of  $T$  and  $r$
5. The equation of state at large temperatures
6. Conclusions

## Standard picture of the phase diagram and its uncertainties

physical quark masses: important for the nature of the transition

$n_f=2+1$  theory with  $m_q=0$  or  $\infty$  gives a first order transition

for intermediate quark masses we have an analytic cross over (no  $\chi$ PT)

F. Karsch et al., Nucl. Phys. Proc. 129 (2004) 614; Lattice'07 G. Endrodi, O. Philipsen

continuum limit is important for the order of the transition:

$n_f=3$  case (standard action,  $N_t=4$ ): critical  $m_{ps} \approx 300$  MeV

with different discretization error (p4 action,  $N_t=4$ ): critical  $m_{ps} \approx 70$  MeV

the physical pseudoscalar mass is just between these two values

what happens for physical quark masses, in the continuum, at what  $T_c$ ?

$N_t=4,6,8,10$  lattices correspond to  $a \approx 0.3$  fm, 0.2 fm, 0.15 fm, 0.12 fm

CPU:  $\approx N_t^{13}$  (thermodynamics):  $N_t=10$  needs 50-100 $\times$  more than  $N_t=6$

## The nature of the QCD transition

Y.Aoki, G.Endrodi, Z.Fodor, S.D.Katz, K.K.Szabo, Nature, 443 (2006) 675 [hep-lat/0611014]

F. Wilczek, Nature, 443 (2006) 675

Symanzik improved gauge, stout improved  $n_f=2+1$  staggered fermions simulations along the line of constant physics:  $m_\pi=135$  MeV,  $m_K=500$  MeV

extrapolation from  $N_t$  and  $N_t+2$  (standard action)  $\approx$  as good as  $N_t$  with p4  
 $N_t=8, 10$  gives  $\approx \pm 1\%$ , but  $a < 0.15, 0.12$  fm needed to set the scale ( $\pm 1\%$ )  
 thermodynamic quantities are obtained "more precisely" than the scale  
 (p4 independent config. is  $>10\times$  more CPU  $\Rightarrow$  instead balance:  $a \rightarrow 0$ )

- finite size scaling for the chiral susceptibility:  $\chi=(T/V)\partial^2\log Z/\partial m^2$

first order transition  $\implies$  peak width  $\propto 1/V$ , peak height  $\propto V$

cross-over  $\implies$  peak width  $\approx$  constant, peak height  $\approx$  constant

eight times larger volumes: **volume independent scaling  $\implies$  cross-over**

do we get the same result (cross-over) in the continuum limit?

one might have the unlucky case as we had in  $n_f=3$  QCD:

discretization errors changed the nature of the transition for physical  $m_{ps}$

- finite size scaling analysis with continuum extrapolated  $m^2\Delta\chi$

the result is consistent with an approximately constant behavior for a factor of 5 difference within the volume range

chance probability for  $1/V$  is  $10^{-19}$  for  $O(4)$  is  $7 \cdot 10^{-13}$

continuum result with physical quark masses in staggered QCD:

the QCD transition at  $\mu=0$  is a cross-over

## The transition temperature ( $N_t=4,6,8,10$ )

Y. Aoki, Z. Fodor, S.D. Katz, K.K. Szabo, Phys. Lett. B. 643 (2006) 46 [hep-lat/0609068]

- a cross-over has no unique  $T_c$ : example of water-steam transition

above the critical point  $c_p$  and  $d\rho/dT$  give different  $T_c$ s.

QCD: chiral & quark number susceptibilities or Polyakov loop  
they result in different  $T_c$  values  $\Rightarrow$  physical difference

extrapolations from large  $a$ :  $\sigma$ ,  $m_\rho$ ,  $r_0$ ,  $m_N$  or  $f_K$  give different  $a$  (in fm)  
this lead to different  $T_c$  values  $\Rightarrow$  non-physical ambiguity  
will be removed in the continuum limit (most precise scale is set by  $f_K$ )

## Chiral susceptibility

$$T_c = 151(3)(3) \text{ MeV}$$

$$\Delta T_c = 28(5)(1) \text{ MeV}$$

## Quark number susceptibility

$$T_c = 175(2)(4) \text{ MeV}$$

$$\Delta T_c = 42(4)(1) \text{ MeV}$$

## Polyakov loop

$$T_c = 176(2)(4) \text{ MeV}$$

$$\Delta T_c = 38(5)(1) \text{ MeV}$$

$N_t=6,8,10$  are in the  $a^2$  scaling regime,  $N_t=8,10$  are practically the same

⇒ 25(4) MeV difference between the chiral & the deconfinement transitions

normalization changes  $T_c$  (multiply a Gaussian by  $T^2$  ⇒ peak shifts)

continuum: e.g.  $\Delta\chi/T^2$  gives  $\approx 10$  MeV higher  $T_c$  than  $m^2\Delta\chi/T^4$  (blue curve)

the difference can be seen only at small lattice spacings

C. De Tar hotQCD  $N_f=8$  (asqtad):  $T_c$  from  $\chi$  tends to be at smaller values

precise data at  $N_f=8$  and 10 are needed to see the difference

- $T_c(\chi_{\bar{\psi}\psi})$  consistent with MILC '2004:  $T_c = 169(12)(4)$  MeV

- BBCR collaboration: recent result [M. Cheng et.al, Phys. Rev. D74 (2006) 054507]

Transition temperature from  $\chi_{\bar{\psi}\psi}$  and Polyakov loop, from both quantities

$T_c=192(7)(4)$  MeV,  $\implies$  for  $\chi_{\bar{\psi}\psi}$  contradicts our result ( $\approx 40$  MeV)

### Main differences to our work

no renormalization,  $\chi/T^2$  is used: explains only  $\approx 10$  MeV difference

only  $N_t = 4$  & 6 (cutoff:  $a \approx 0.3$  fm & 0.2 fm or  $a^{-1} \approx 700$  MeV & 1 GeV)

scale is set by  $r_0$  instead of  $f_K$  (influences only the overall accuracy)

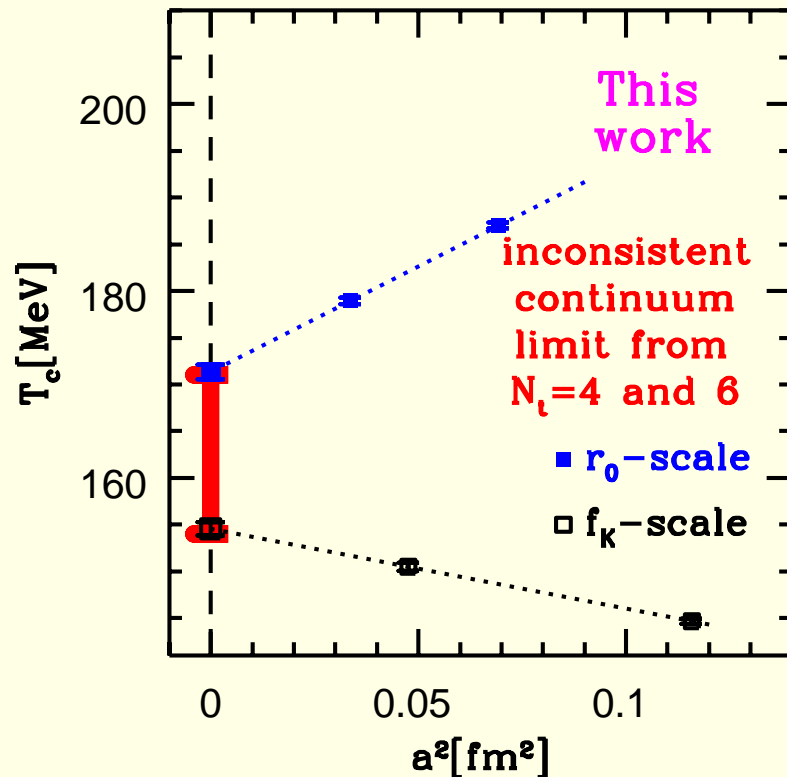

What is the reason for this discrepancy?

Their last concluding remark: it is desirable to

“obtain a reliable independent scale setting for the transition temperature from an observable not related to properties of the static potential”.

What if one used the static potential ( $r_0$ ) and  $f_K$  to set the scale?  
 compare  $N_t=4,6$  and  $4,6,8,10$  extrapolations with different scale settings

Continuum limits from  $N_t = 4, 6$  are inconsistent, from  $N_t = 6, 8, 10$  consistent  
 not surprising: eg. asqtad at  $N_t \approx 10$  has  $\approx 10\%$  scale difference between  $r_1$  &  $f_K$   
 Lüscher (Dublin) & DelDebbio et al:  $a = .06\text{fm}$   $\approx 20\%$  difference between  $r_0$  &  $m_{K^*}$

one needs 3 points in the scaling regime (2 points are always on a line)

## What if they used $f_K$ to set the scale?

We repeated some of their  $T = 0$  simulations to determine  $f_K$

Alternatively:

We can use  $r_0$  and only  $N_t=4,6$

Continuum extrapolations from  $N_t = 4, 6$  are inconsistent!

not surprising: eg. asqtad at  $N_t \approx 10$  has  $\approx 10\%$  scale difference between  $r_1$  &  $f_K$   
Lüscher (Dublin) & DelDebbio et al:  $a = .06\text{fm}$   $\approx 20\%$  difference between  $r_0$  &  $m_{K^*}$

What if they used  $f_K$  to set the scale?

We repeated some of their  $T = 0$  simulations to determine  $f_K$

Alternatively:

We can use  $r_0$  and only  $N_t = 4, 6, 8, 10$

Continuum extrapolations from  $N_t = 6, 8, 10$  are consistent!

Conclusion: continuum limit from  $N_t = 4, 6$  isn't safe ( $a \approx 0.3, 0.2$  fm or  $0.7, 1$  GeV)

- transition temperature depends on the geometry

eg. nanotube-water didn't freeze, even at hundreds of degrees below  $0^{\circ}\text{C}$

A. Bazavov and B. Berg, Phys.Rev. D76 014502 (2007)

determined the transition temperature pure SU(3), no quarks with “confined” spatial boundary conditions: more like experiments instead of periodic one (which we use to reach  $V \rightarrow \infty$  fast)

large deviation (upto 30 MeV) from the infinite volume limit

⇒ calculate it in full QCD (cross-over) for different geometries

- several observables can be determined with  $N_t=4,6,8,10$  configurations
  - a. curvature on the  $\mu$ -T diagram (ongoing analysis)
  - b. static quark free energies

Polyakov loop correlator:

$$\sum_x \langle \text{Tr}P(x) \text{Tr}P(x+r) \rangle \propto e^{-F_{q\bar{q}}(r)/T}$$

measure correlators on  $N_t=4,6,8,10$  lattices  $\implies$  continuum limit of  $F_{q\bar{q}}$

## Link to perturbation theory: equation of state at large temperatures

lattice results for the EoS  
extend upto a few times  $T_c$

perturbative series “converges”  
only at asymptotically high T

- the standard technique is the integral method:

$\bar{p} = T/V \cdot \log(Z)$ , but  $Z$  is difficult  $\Rightarrow \bar{p}$  integral of  $(\partial \log(Z)/\partial \beta, \partial \log(Z)/\partial m)$   
subtract the  $T=0$  term, the pressure is given by:  $p(T) = \bar{p}(T) - \bar{p}(T=0)$

- back of an envelope estimate:

$T_c \approx 150 - 200$  MeV,  $m_\pi = 135$  MeV and try to reach  $T = 20 \cdot T_c$  for  $N_t = 8$  ( $a = 0.0075$  fm)  
 $\Rightarrow N_s > 4/m_\pi \approx 6/T_c = 6 \cdot 20/T = 6 \cdot 20 \cdot N_t \approx 1000 \Rightarrow$  completely out of reach

a. subtract successively:  $p(T) = \bar{p}(T) - \bar{p}(T=0) = [\bar{p}(T) - \bar{p}(T/2)] + [\bar{p}(T/2) - \bar{p}(T/4)] + \dots$

$\implies$  for subtractions at most twice as large lattices are needed

b. instead of the integral method calculate:  $\bar{p}(T) - \bar{p}(T/2) = T/(2V) \cdot \log[Z^2(N_t)/Z(2N_t)]$

$$\frac{Z^2(N_t)}{Z(2N_t)} = \frac{\begin{array}{c} N_t-2 \quad N_t-1 \\ \begin{array}{|c|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array} \\ \begin{array}{|c|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array} \\ \hline \begin{array}{|c|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array} \\ \begin{array}{|c|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array} \\ \hline \begin{array}{|c|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array} \\ \begin{array}{|c|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array} \\ \hline \end{array} = \frac{\begin{array}{|c|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array} \begin{array}{|c|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array}}{\begin{array}{|c|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array} \begin{array}{|c|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array}}$$

$$\bar{Z}(\alpha) = \begin{array}{|c|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array} \begin{array}{|c|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array} \begin{array}{|c|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array} \begin{array}{|c|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array}$$

(1- $\alpha$ )  
 $\alpha$        $\alpha$   
(1- $\alpha$ )

define  $\bar{Z}(\alpha) = \int \mathcal{D}U \exp[-\alpha S_{1b} - (1-\alpha) S_{2b}] \implies Z^2(N_t) = \bar{Z}(0)$  and  $Z(2N_t) = \bar{Z}(1)$

one gets directly  $\bar{p}(T) - \bar{p}(T/2) = T/(2V) \int_0^1 d \log[\bar{Z}(\alpha)] / d\alpha \cdot d\alpha = T/(2V) \int_0^1 \langle S_{1b} - S_{2b} \rangle \alpha \cdot d\alpha$

a. subtract successively:  $p(T) = \bar{p}(T) - \bar{p}(T=0) = [\bar{p}(T) - \bar{p}(T/2)] + [\bar{p}(T/2) - \bar{p}(T/4)] + \dots$

$\implies$  for subtractions at most twice as large lattices are needed

b. instead of the integral method calculate:  $\bar{p}(T) - \bar{p}(T/2) = T/(2V) \cdot \log[Z^2(N_t)/Z(2N_t)]$

$$\frac{Z^2(N_t)}{Z(2N_t)} = \frac{\begin{array}{c} \begin{array}{|c|c|} \hline N_t-2 & N_t-1 \\ \hline \end{array} \\ \begin{array}{|c|c|} \hline 2 & 0 \\ \hline \end{array} \\ \begin{array}{|c|c|} \hline 1 & 1 \\ \hline \end{array} \\ \hline \begin{array}{|c|c|c|c|} \hline & & & \\ \hline \end{array} \\ \begin{array}{|c|c|} \hline 2 & 0 \\ \hline \end{array} \\ \begin{array}{|c|c|} \hline 1 & 2N_t-1 \\ \hline \end{array} \\ \hline \end{array}}{\quad} \quad \bar{Z}(\alpha) = \begin{array}{|c|c|c|c|} \hline & & (1-\alpha) & \\ \hline \alpha & & & \alpha \\ \hline & & (1-\alpha) & \\ \hline \end{array}$$

define  $\bar{Z}(\alpha) = \int \mathcal{D}U \exp[-\alpha S_{1b} - (1-\alpha) S_{2b}] \implies Z^2(N_t) = \bar{Z}(0)$  and  $Z(2N_t) = \bar{Z}(1)$

one gets directly  $\bar{p}(T) - \bar{p}(T/2) = T/(2V) \int_0^1 d \log[\bar{Z}(\alpha)]/d\alpha \cdot d\alpha = T/(2V) \int_0^1 \langle S_{1b} - S_{2b} \rangle \alpha \cdot d\alpha$

a. subtract successively:  $p(T) = \bar{p}(T) - \bar{p}(T=0) = [\bar{p}(T) - \bar{p}(T/2)] + [\bar{p}(T/2) - \bar{p}(T/4)] + \dots$

$\implies$  for subtractions at most twice as large lattices are needed

b. instead of the integral method calculate:  $\bar{p}(T) - \bar{p}(T/2) = T/(2V) \cdot \log[Z^2(N_t)/Z(2N_t)]$

$$\frac{Z^2(N_t)}{Z(2N_t)} = \frac{\begin{array}{c} N_t-2 \quad N_t-1 \\ \begin{array}{|c|c|} \hline \blacksquare & \blacksquare \\ \hline \end{array} \\ \begin{array}{|c|c|} \hline \blacksquare & \blacksquare \\ \hline \end{array} \\ 2 \quad 0 \\ \hline \begin{array}{|c|c|} \hline \blacksquare & \blacksquare \\ \hline \end{array} \\ \begin{array}{|c|c|} \hline \blacksquare & \blacksquare \\ \hline \end{array} \\ 2 \quad 0 \quad 2N_t-1 \\ \hline \end{array}}{\begin{array}{c} \begin{array}{|c|c|} \hline \blacksquare & \blacksquare \\ \hline \end{array} \\ \begin{array}{|c|c|} \hline \blacksquare & \blacksquare \\ \hline \end{array} \\ \hline \begin{array}{|c|c|} \hline \blacksquare & \blacksquare \\ \hline \end{array} \\ \begin{array}{|c|c|} \hline \blacksquare & \blacksquare \\ \hline \end{array} \\ \hline \end{array}}$$

define  $\bar{Z}(\alpha) = \int \mathcal{D}U \exp[-\alpha S_{1b} - (1-\alpha) S_{2b}] \implies Z^2(N_t) = \bar{Z}(0)$  and  $Z(2N_t) = \bar{Z}(1)$

one gets directly  $\bar{p}(T) - \bar{p}(T/2) = T/(2V) \int_0^1 d \log[\bar{Z}(\alpha)] / d\alpha \cdot d\alpha = T/(2V) \int_0^1 \langle S_{1b} - S_{2b} \rangle \alpha \cdot d\alpha$

a. subtract successively:  $p(T) = \bar{p}(T) - \bar{p}(T=0) = [\bar{p}(T) - \bar{p}(T/2)] + [\bar{p}(T/2) - \bar{p}(T/4)] + \dots$

$\implies$  for subtractions at most twice as large lattices are needed

b. instead of the integral method calculate:  $\bar{p}(T) - \bar{p}(T/2) = T/(2V) \cdot \log[Z^2(N_t)/Z(2N_t)]$

$$\frac{Z^2(N_t)}{Z(2N_t)} = \frac{\begin{array}{c} N_t-2 \quad N_t-1 \\ \begin{array}{|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array} \\ 2 \quad 1 \\ \begin{array}{|c|c|} \hline \blacksquare & \blacksquare \\ \hline \end{array} \\ 0 \end{array}}{\begin{array}{c} \begin{array}{|c|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array} \\ 2 \\ \begin{array}{|c|c|} \hline \blacksquare & \blacksquare \\ \hline \end{array} \\ 1 \\ \begin{array}{|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array} \\ 0 \quad 2N_t-1 \end{array}}$$

$$\bar{Z}(\alpha) = \begin{array}{c} (1-\alpha) \\ \begin{array}{|c|c|c|} \hline \blacksquare & \blacksquare & \blacksquare \\ \hline \end{array} \\ \alpha \quad \alpha \\ \begin{array}{|c|c|} \hline \blacksquare & \blacksquare \\ \hline \end{array} \\ (1-\alpha) \end{array}$$

define  $\bar{Z}(\alpha) = \int \mathcal{D}U \exp[-\alpha S_{1b} - (1-\alpha) S_{2b}] \implies Z^2(N_t) = \bar{Z}(0)$  and  $Z(2N_t) = \bar{Z}(1)$

one gets directly  $\bar{p}(T) - \bar{p}(T/2) = T/(2V) \int_0^1 d \log[\bar{Z}(\alpha)] / d\alpha \cdot d\alpha = T/(2V) \int_0^1 \langle S_{1b} - S_{2b} \rangle \alpha \cdot d\alpha$

long awaited link between lattice thermodynamics and pert. theory is there

- a. subtract successively:  $p(T) = \bar{p}(T) - \bar{p}(T=0) = [\bar{p}(T) - \bar{p}(T/2)] + [\bar{p}(T/2) - \bar{p}(T/4)] + \dots$   
 $\implies$  for subtractions at most twice as large lattices are needed
- b. instead of the integral method calculate:  $\bar{p}(T) - \bar{p}(T/2) = T/(2V) \cdot \log[Z^2(N_t)/Z(2N_t)]$

$$\frac{Z^2(N_t)}{Z(2N_t)} = \frac{\text{Diagram 1}}{\text{Diagram 2}} \quad \bar{Z}(\alpha) = \text{Diagram 3}$$

The diagrams illustrate the relationship between the partition functions and the auxiliary function  $\bar{Z}(\alpha)$ . Diagram 1 shows two separate square lattices of size  $N_t$  with vertices labeled  $N_t-2$ ,  $N_t-1$ ,  $0$ , and  $1$ . Diagram 2 shows a single larger square lattice of size  $2N_t$  with vertices labeled  $2$ ,  $1$ ,  $0$ , and  $2N_t-1$ . Diagram 3 shows a square lattice with a central blue square of side length  $\alpha$  and a surrounding black square of side length  $1-\alpha$ , with vertices labeled  $\alpha$  and  $1-\alpha$ .

define  $\bar{Z}(\alpha) = \int \mathcal{D}U \exp[-\alpha S_{1b} - (1-\alpha) S_{2b}] \implies Z^2(N_t) = \bar{Z}(0)$  and  $Z(2N_t) = \bar{Z}(1)$

one gets directly  $\bar{p}(T) - \bar{p}(T/2) = T/(2V) \int_0^1 d \log[\bar{Z}(\alpha)] / d\alpha \cdot d\alpha = T/(2V) \int_0^1 \langle S_{1b} - S_{2b} \rangle_\alpha \cdot d\alpha$

long awaited link between lattice thermodynamics and pert. theory is there

## Conclusions

- The QCD transition is a cross-over
- finite size scaling analysis of the chiral susceptibility
- continuum limit using  $N_t = 4, 6, 8, 10$
- no volume dependence  $\Rightarrow$  no real phase transition scenario

- The transition temperature is determined

- Chiral susceptibility:

$$T_c=151(3)(3) \text{ MeV}, \Delta T_c=28(5)(1) \text{ MeV}$$

- Quark number susceptibility:

$$T_c=175(2)(4) \text{ MeV}, \Delta T_c=42(4)(1) \text{ MeV}$$

- Polyakov loop:

$$T_c=176(2)(4) \text{ MeV}, \Delta T_c=38(5)(1) \text{ MeV}$$

- Use finer lattices ( $N_t = 8, 10$ ) for the proper continuum limit  
new results are expected from the hotQCD Collaboration  
important to gain a consistent picture (independent calculations)

- Other observables with  $N_T=4,6,8,10$  configurations
- ongoing continuum analysis for the curvature on the  $\mu$ -T plane
- continuum result for the static quark free energies
- Gap between lattice and perturbative bulk thermodynamics
- two new methods to reach (arbitrary) high temperatures
- connection to perturbation theory is established

- an even more often experienced example

melting of ice shows singular behavior: ice  $\longrightarrow$  water

melting of butter shows analytic behaviour (broad transition, cross-over)

natural fats are mixed triglycerids of fatty acids from  $C_4$  to  $C_{24}$

these are saturated or unsaturated of even carbon numbers

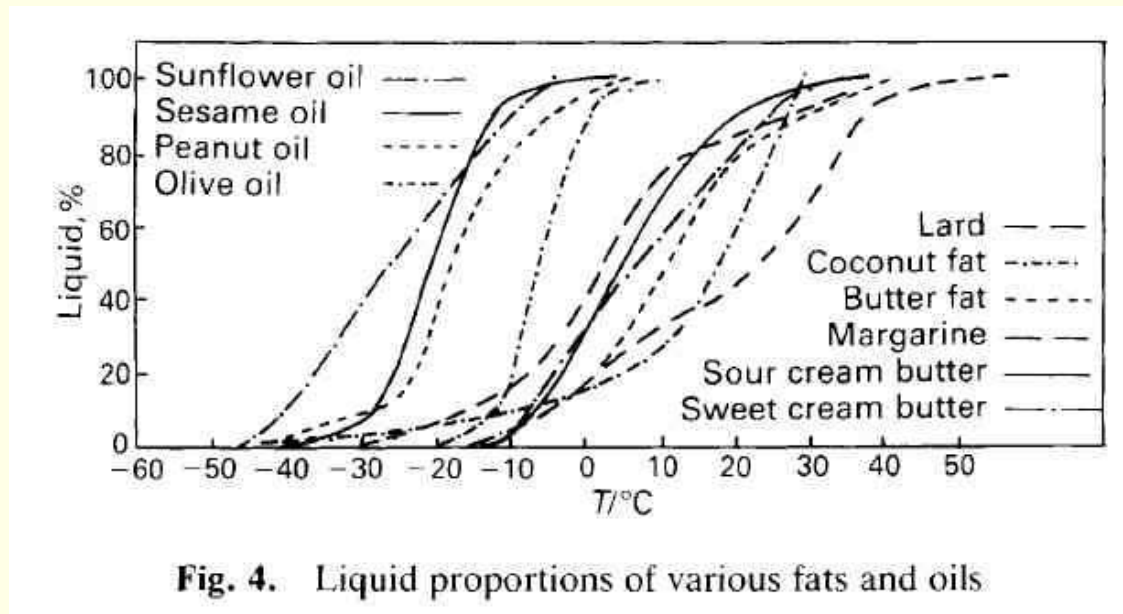

Fig. 4. Liquid proportions of various fats and oils

since in QCD we have an analytic cross-over

we will see very similar temperature dependence for all quantities

e.g. chiral condensate, strange quark susceptibility or Polyakov loop

## The transition temperature

Y. Aoki, Z. Fodor, S.D. Katz, K.K. Szabo, Phys. Lett. B. 643 (2006) 46 [hep-lat/0609068]

$T = 0$ :

set the physical scale and locate the physical point

Three quantities are needed ( $m_\pi$  and  $m_K$  for the quark masses)

Several possibilities for the third quantity

- string tension (not existing in full QCD)
- static quark potential at intermediate distances ( $r_0^2 \cdot dV/dr=1.65$ )
- directly measurable quantities (e.g.  $f_K$ )

Further quantities are predictions (e.g.  $r_0, f_\pi, m_{K^*}$ )

$T > 0$ :

cross-over  $\rightarrow$  different definitions give different  $T_c$

Possible choices:

- Chiral susceptibility
- Quark number susceptibility
- Polyakov-loop

## T=0 Simulations

- $m_\pi$ ,  $m_K$  and  $f_K$  was used to set the quark masses and scale
- $m_{ud} \approx 3, 5, 7, 9 \times m_{ud,phys}$  together with chiral extrapolation
- lattices from  $12^3 \cdot 24$  up to  $24^3 \cdot 32$

Predictions for  $m_{K^*}$ ,  $f_\pi$  and consistent with experimental values  
 $r_0$  is consistent with MILC measurement

- How to get rid of the discretization errors?

a. susceptibility for fixed physical volumes in the continuum

b. finite size analysis of the continuum extrapolated values

renormalize the susceptibility the same way as the free energy

$$f(T) \propto \log Z(T \neq 0)/V_4 - \log Z(T=0)/\bar{V}_4$$

$p(T)$  has a continuum limit and we can use  $m_r = Z_m \cdot m$

$$\chi_r(T) = \partial^2 / (\partial m_r^2) [\log Z(T \neq 0)/V_4 - \log Z(T=0)/\bar{V}_4]$$

construct a quantity in continuum:  $Z_m$  drops out from  $m^2 \partial^2 / \partial m^2$

$$\implies m_r^2 \cdot \chi_r(T) = m^2 \cdot [\chi(T \neq 0) - \chi(T=0)]$$

Chiral susceptibility:

Renormalization: seen before

Quark number susceptibility:

$$\frac{\chi_s}{T^2} = \frac{1}{TV} \left. \frac{\partial^2 \log Z}{\partial \mu_s^2} \right|_{\mu_s=0}$$

No renormalization necessary

Polyakov loop:

$$P = \frac{1}{N_s^3} \sum_{\mathbf{x}} \text{tr}[U_4(\mathbf{x}, 0)U_4(\mathbf{x}, 1) \dots U_4(\mathbf{x}, N_t - 1)]$$

Related to the static quark free energy:

$$|\langle P \rangle|^2 = \exp(-\Delta F_{q\bar{q}}(r \rightarrow \infty)/T)$$

Renormalization condition for the potential:  $V_R(r_0) = 0$

$$|\langle P_R \rangle| = |\langle P \rangle| \exp(V(r_0)/(2T))$$

- we need a continuum extrapolation (width, height)

calculate  $m^2\Delta\chi = m^2[\chi(T\neq 0)-\chi(T=0)]$  at the transition point

continuum limit values are obtained from  $N_t=4,6,8,10$

$N_t=6,8,10$  temporal sizes are already in the  $a^2$  scaling region

choice of the action or the line of constant physics is ambiguous  
this choice has influence only on the slope, not on the value

the three continuum extrapolated values do not show  $1/V$  scaling

## Continuum extrapolations

$N_t=4$  is off,  $N_t=6,8$  and 10 show nice scaling for all quantities

Chiral and de-confinement transitions at different locations

25(4) MeV difference

**Note:** different normalization leads to different  $T_c$   
(e.g.  $\Delta\chi/T^2$  leads to  $\approx 10$  MeV higher  $T_c$ )

→  $T_c(\Delta\chi)$  consistent with MILC '2004:  $T_c = 169(12)(4)$   
Their analysis used coarser lattices, non-physical quark masses, smaller aspect ratios and inexact R algorithm
